## Modular Supercomputing

The NASA Advanced Supercomputing Division's innovative modular approach to expand NASA's high-end critical computing capabilities reflects the agency's continued leadership in the high performance computing arena. Two modular supercomputing facilities built at NASA's Ames Research Center in Silicon Valley house a pair of peta-scale supercomputers to help solve the agency's most challenging problems in an environmentally conscious way that also provides flexibility, power efficiency, and cost savings.

Working with industry partners, the NASA Advanced Supercomputing (NAS) Division designed, built, and installed the first proof-of-concept Modular Supercomputing Facility, housing the Electra supercomputer, in 2016. This prototype module uses a combination of outdoor air and fan technology to remove the heat generated by the system, taking advantage of the San Francisco Bay Area's temperate weather. With this cooling technology, the system and module consume less than 10% of the energy needed to cool the same amount of resources on NAS's traditional computer floor. The facility was expanded with a second module, populated with HPE E-Cells in 2017 and 2018. This second module combines the outdoor air cooling technology with a circulating water system, which uses two adiabatic coolers on its roof to send chilled water down to the computer racks.

*The Electra supercomputer is a petascale proof-of-concept system for the agency's modular computing technology, which saves significant amounts of water and power annually.*  
Marco Librero, NASA Ames

The success of the prototype modular facility led the NAS Division to build the infrastructure to support deployment of NASA's next major computer system on a one-acre site. The initial module and racks of the new Aitken system were installed in 2019, with expansions in 2020 and 2022 more than doubling the system's computing power. The site where Aitken is installed will be able to hold 16 modules for computing and data storage. With NASA's ever-increasing demand for more computing resources, modular supercomputing significantly reduces the annual water and energy consumption needed to maintain these systems, while also allowing for the flexibility to add new resources with minimal impact to users. The resulting cost savings translate to purchasing power for additional capabilities to deliver world-class supercomputing for the more than 1,500 users across the U.S. who rely on NASA high-end computing to make new scientific discoveries and expand human knowledge.

### Aitken Architecture Overview

- HPE E-Cells with Intel Xeon Cascade Lake processors; 16 HPE Apollo 9000 racks with AMD Rome processors
- 3,200 nodes, 308,224 cores, and 1.3 PB of memory
- 13.1 petaflops theoretical peak performance
- 9.1 petaflops sustained performance (April 2022)

### Aitken Module Efficiency Stats

- Power Usage Effectiveness (PUE) ratio: 1.05
- As compared to the same amount of computing resources in the main NAS building, the module housing Aitken annually:
  - Consumes 14% of the energy needed for cooling, saving over \$500K or 4.5 million kilowatt-hours
  - Reduces water usage for cooling by 96%, saving over 6 million gallons

### Electra Architecture Overview

- 16 SGI D-Racks with Intel Xeon Broadwell processors; 8 HPE E-Cells with Intel Xeon Skylake processors
  - 3,456 nodes, 124,416 cores, and 589 TB of memory
  - 8.32 petaflops theoretical peak performance
  - 5.44 petaflops sustained performance (Nov 2020)

### Electra Module Efficiency Stats

- Power Usage Effectiveness (PUE) ratio: 1.04
- As compared to the same amount of computing resources in the main NAS building, the module housing Electra annually:
  - Consumes 16% of the energy needed for cooling, saving over \$250K or 3.3 million kilowatt-hours
  - Reduces water usage for cooling by 77%, saving over three million gallons
